

# Conditioning IOTC Albacore OMs using the ABC approach

R. Hillary & I. Mosqueira

CSIRO Environment (AU) & Wageningen Marine Research (NL)

October 24, 2024

# Outline

- Presentation of paper *IOTC-2024-WPM15-08*
- Conditioning of ALB OMs using ABC MCMC approach:
  - 1 Model structure(s) & time-line
  - 2 Input data
  - 3 Stock status prior scenarios
  - 4 Axes of uncertainty
  - 5 Results
  - 6 Next steps

# OM model structure: population dynamics

- Timeline: 2000 to 2020 (covers all existing cohorts)
- Age, sex and quarterly structured population model
- Beverton-Holt with exploited equilibrium initialisation
- Designed to mimic current assessment model structure
- Reproduces all key stock status variables:
  - 1 MSY variables:  $B_{\text{msy}}$ ,  $H_{\text{msy}}$ , &  $C_{\text{msy}}$
  - 2 Relative biomass (eg. relative to  $B_0$ )

# OM model structure: fishery dynamics

- Merge “common” seasonal LL fleets 1–4
- Retain single PS and “Other” fleet: 6 in total
- Size data from LL and PS data (aggregated across time)
- LL CPUE from a given fleet (not jointly at this time)
- Seasonal vs. annual catchability explored

# Stock status prior information

- Key feature of ABC approach
- Impose status priors (eg. from assessment) on OM
- Explore 4 types:
  - 1 Relative SSB: prior mean/SD for any range of years
  - 2  $B_{\text{msy}}$  ratio: prior mean/SD for any range of years
  - 3  $H_{\text{msy}}$  ratio: prior mean/SD for any range of years
  - 4 Overfishing probability: penalise *only if*  $H > H_{\text{msy}}$
- Integrate status information with LF & CPUE data
- Here is where it diverges from assessment-to-OM approach

# Suite of stock status priors

- Relative SSB: year 2000 mean (CI) of 0.5 (0.3–0.7)
- $B_{\text{msy}}$  ratio: 2019, 2020 mean 2.25, 2 with SD 0.35
- $H_{\text{msy}}$  ratio: 2000, 2020 mean of 0.6 with SD 0.2
- Overfishing penalty:  $\mathbb{P}(H/H_{\text{msy}} > 2) \leq 0.05$
- This removes small numbers of runs with very high  $H$

# Covering previous axes of uncertainty

- 1 Steepness &  $M$ : covariance joint prior (not discrete grid)
- 2  $\sigma_r^2$ : (i) fixed at 0.3; (ii) estimated with prior CI 0.2–0.5
- 3 LF: weight/influence (aggregating and ABC discrepancy)
- 4 LL catchability: alternative 1% annual increasing trend
- 5 CPUE series: seasonal  $q$  using fleet 1 and 3 *separately*

## Constructing $\pi(h, M)$ prior

- Define marginal priors for both parameters
- $h$  mean 0.8, CI 0.7–0.9;  $M$  mean 0.3, CI 0.27–0.33
- Process:
  - 1 Calculate  $\tilde{\Delta} = B_{\text{msy}}/B_0$  for mean  $h$  &  $M$
  - 2 Simulate  $h$  and  $M$  from marginal priors
  - 3 Define a tolerance interval  $\varepsilon$
  - 4 Accept values of  $\{h, M\}$  within  $\varepsilon$  of  $\tilde{\Delta}$
  - 5 Calculate correlation in retained samples of  $\{h, M\}$
- For  $\varepsilon = 0.05$  correlation coefficient is -0.58

# OM conditioning scenarios

- Explored seven individual scenarios for conditioning:
  - 1 **R1**: CPUE fleet 1, SSB but *not*  $H_{\text{msy}}$  priors
  - 2 **R1a**: CPUE fleet 3, SSB *and*  $H_{\text{msy}}$  priors
  - 3 **R1b**: same as **R1** with additional overfishing penalty
  - 4 **R2**: same as **R1** but  $\sigma_r^2$  estimated
  - 5 **R2a**: same as **R1a** but  $\sigma_r^2$  estimated
  - 6 **R2b**: same as **R1b** but  $\sigma_r^2$  estimated
  - 7 **R3**: same as **R1** with 1% *p.a.*  $\uparrow q$  trend
  - 8 **R3a**: same as **R1a** with 1% *p.a.*  $\uparrow q$  trend

# Approximate Bayesian Computation (ABC)

- Relaxes idea of strict likelihood:  $\ell(D | \theta)$
- Focus is on derived quantities:  $X = f(\theta)$
- Instead define a discrepancy function:  $\pi(D, X)$
- Prior  $\pi(\theta)$  has a wider role in ABC format
- Now includes stock status prior information
- Approximate posterior defined as follows:

$$\tilde{\pi}(\theta | D) \propto \pi(D, X)\pi(\theta)$$

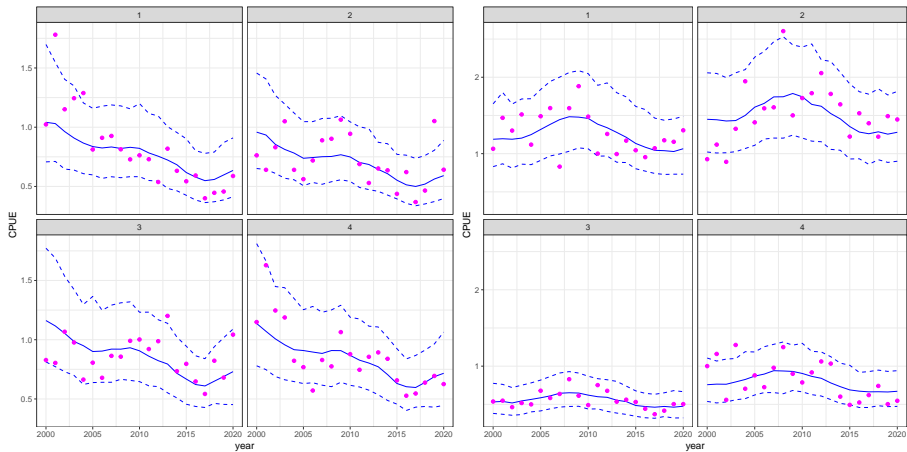

- Custom MCMC algorithm to sample from  $\tilde{\pi}(\theta | D)$

# Discrepancy function & priors

- Deconstructing the discrepancy function,  $\pi(D, X)$
- Data elements:
  - ① CPUE: single fleet quarterly biomass index
  - ② LF: time-averaged Kullback-Leibler divergence
- Parameter and process variable prior,  $\pi(\theta)$ :
  - ① Direct parameter prior quasi-uninformative
  - ② Implied prior on  $\theta$  via stock status priors
  - ③ Informative prior on  $\sigma_r^2$  (inverse-gamma)

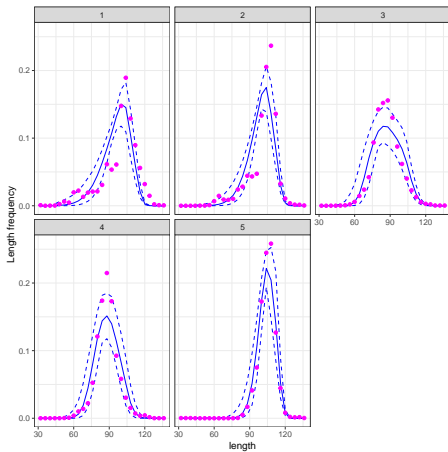

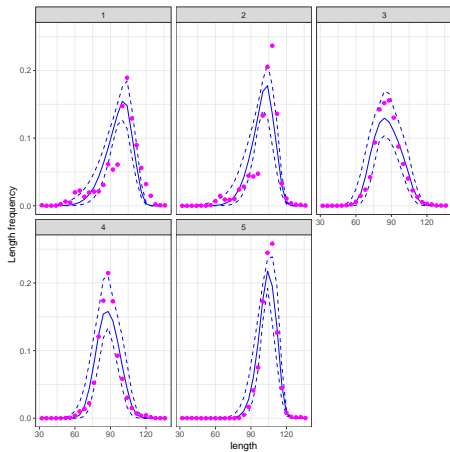

# Fits to data: CPUE indices

- Fleet 1 (**R1**, left) & fleet 3 (**R1a**, right):

# Fits to data: Length frequency data

- Scenario **R1** (left) & **R1a** (right):

# Population dynamics

- Scenario **R1** (top) & **R1a** (bottom):
- SSB depletion (l),  $B_{msy}$  ratio (m), recruitment (r)

# Selectivity (size-based)

- Scenario **R1** (top) & **R1a** (bottom):

# Estimates of $\sigma_r^2$

- Scenario **R2** (top) & **R2a** (bottom):

# OM conditioning summary

- General summary across all OM scenarios:

OM scenario	$\Delta_{2000}$	$\Delta_{2020}$	$\tilde{\Delta}_{2020}$	$\mathcal{H}_{2020}$
Prior	0.5 (0.3–0.7)	n/a	2 (1.3–2.7)	0.6 (0.2–1)
R1	0.76 (0.61–0.97)	0.41 (0.22–0.56)	1.9 (1.02–2.58)	1.13 (0.5–3.78)
R1a	0.56 (0.4–0.72)	0.48 (0.3–0.69)	2.01 (1.42–2.61)	0.68 (0.33–1.38)
R1b	0.74 (0.61–0.9)	0.42 (0.24–0.54)	1.98 (1.16–2.49)	0.98 (0.46–2.4)
R2	0.71 (0.57–0.84)	0.41 (0.21–0.55)	1.91 (0.99–2.53)	1.22 (0.45–3.57)
R2a	0.56 (0.41–0.72)	0.47 (0.28–0.71)	2.03 (1.3–2.54)	0.65 (0.34–1.4)
R2a	0.58 (0.40–0.69)	0.46 (0.28–0.74)	1.98 (1.35–2.59)	0.72 (0.39–1.34)
R3	0.78 (0.6–0.91)	0.38 (0.15–0.52)	1.77 (0.7–2.44)	1.4 (0.58–5.06)
R3a	0.63 (0.48–0.77)	0.42 (0.25–0.59)	1.94 (1.23–2.5)	0.71 (0.35–1.45)

# OM conditioning summary

- **R1**: CPUE inform scale, high upper CI  $\mathcal{H}_y$  by 2020
- **R1a**: CPUE uninformative on scale requires  $H_{\text{msy}}$  priors
- **R1b**: very similar to **R1**, removes v. high late  $\mathcal{H}_y$
- **R2**: pushes for higher  $\sigma_r^2$  median 0.41 vs. 0.3
- **R2a**: very consistent with 0.3 - just increases certainty
- **R2b**: potential reference case
- **R3**: similar to **R1** but more pessimistic recently
- **R3a**: similar to **R1a** but more pessimistic recently

# Operating model grid

- Reference case: OM 2b
- Reference set: OMs 1, 2 and 3
- Robustness set: low recruitment period, lower sampling area 1

# Simulation design

- Tuning for 50, 60 and 70% Kobe green
- CPUE-based MP (as SWO)
- Surplus production (JABBA) with buffer HCR

# Overall summary

- Successful application of ABC OM approach to IO ALB
- Focussed on 2000–2020 time-period (all living cohorts)
- Able to fit to all key data sources
- Mimics assessment model structure & status if required
- Able to cover previous uncertainty grid probabilistically
- Coherent range of plausible OMs
- Able to generate key MP data inputs

## Next steps: OM

- Final checks on seasonal OM projections
- Implementing Bayesian cross-validation methods
- Future work: Possible spatial extensions (conflicting CPUE trends)

## Next steps: MPs

- Testing model-free and JABBA-based MPs
- Tuning for all three objectives
- Robustness tests
